

The `irlba` Package

Bryan W. Lewis
blewis@illposed.net,

adapted from the work of:
Jim Baglama (University of Rhode Island)
and Lothar Reichel (Kent State University).

August 23, 2016

1 Introduction

The `irlba` package provides a fast way to compute partial singular value decompositions (SVD) of large matrices. Recent additions to the package can also compute fast partial symmetric eigenvalue decompositions. The package is an R implementation of the *augmented implicitly restarted Lanczos bidiagonalization algorithm* of Jim Baglama and Lothar Reichel¹. Source code is maintained at <https://github.com/bwlewis/irlba>.

The `irlba` package works with real- and complex-valued dense R matrices and real-valued sparse matrices from the `Matrix` package. The package provides several easy ways to define custom matrix arithmetic that works with other matrix classes including `big.matrix` from the `bigmemory` package and others. The `irlba` is both faster and more memory efficient than the usual R `svd` function for computing a few of the largest singular vectors and corresponding singular values of a matrix, and advantage of available high-performance linear algebra libraries if R is compiled to use them. In particular, the package uses the same BLAS and LAPACK libraries that R uses (see <https://cran.r-project.org/doc/manuals/R-admin.html#BLAS>), or the CHOLMOD library from R's `Matrix` package for sparse matrix problems.

A whirlwind summary of the algorithm follows, along with a few basic examples. See the companion package vignette for more substantial applications. A much more detailed description and discussion of the algorithm may be found in the cited Baglama-Reichel reference.

¹Augmented Implicitly Restarted Lanczos Bidiagonalization Methods, J. Baglama and L. Reichel, SIAM J. Sci. Comput. 2005.

2 Partial Singular Value Decomposition

Let $A \in \mathbf{R}^{\ell \times n}$ and assume $\ell \geq n$. These notes simplify the presentation by considering only real-valued matrices and assuming without losing generality that there are at least as many rows as columns (the method works more generally). A singular value decomposition of A can be expressed as:

$$A = \sum_{j=1}^n \sigma_j u_j v_j^T, \quad v_j^T v_k = u_j^T u_k = \begin{cases} 1 & \text{if } j = k, \\ 0 & \text{o.w.,} \end{cases}$$

where $u_j \in \mathbf{R}^\ell$, $v_j \in \mathbf{R}^n$, $j = 1, 2, \dots, n$, and $\sigma_1 \geq \sigma_2 \geq \dots \geq \sigma_n \geq 0$.

Let $1 \leq k < n$. A rank k partial SVD of A is defined as:

$$A_k := \sum_{j=1}^k \sigma_j u_j v_j^T.$$

The following simple example shows how to use `irlba` to compute the five largest singular values and corresponding singular vectors of a 5000×5000 matrix. We compare to the usual R `svd` function and report timings for our test machine, a 4-CPU core, 3.0 GHz AMD A10-7850K personal computer with 16 GB RAM, using R version 3.3.1 using the high performance AMD ACML core math library BLAS and LAPACK.

```
> library('irlba')
> set.seed(1)
> A <- matrix(rnorm(5000*5000), 5000)
> t1 <- proc.time()
> L <- irlba(A, 5)
> print(proc.time() - t1)
   user  system elapsed 
17.440   0.192   4.417 
> gc()
      used (Mb) gc trigger (Mb) max used (Mb)
Ncells 1096734 58.6   1770749 94.6 1442291 77.1
Vcells 26685618 203.6 62229965 474.8 52110704 397.6
```

Now, compare with the standard `svd` function:

```
> t1 <- proc.time()
> S <- svd(A, nu=5, nv=5)
> print(proc.time() - t1)
   user  system elapsed 

```

```
277.092 11.552 74.425
> gc()
      used (Mb) gc trigger (Mb) max used (Mb)
Ncells 1097441 58.7   1770749  94.6   1442291  77.1
Vcells 26741910 204.1 169891972 1296.2 176827295 1349.1

# Compare the (default) relative error in the singular values
> sqrt (crossprod(S$d[1:5]-L$d)/crossprod(S$d[1:5]))
      [,1]
[1,] 4.352641e-10
```

The `irlba` method uses about 1/20 elapsed time as the `svd` method in this example (only about 6 per cent of the total CPU time) and less than one third the peak memory.

2.1 Differences with `svd`

The `irlba` function is designed to compute a *partial* singular value decomposition. It is largely compatible with the usual R `svd` function but there are some differences. In particular:

1. The `irlba` function only computes the number of singular values corresponding to the maximum of the desired singular vectors, `max(nu, nv)`. For example, if 5 singular vectors are desired (`nu=nv=5`), then only the five corresponding singular values are computed. The standard R `svd` function always returns the *total* set of singular values for the matrix, regardless of how many singular vectors are specified.
2. The `irlba` function is an iterative method that continues until either a tolerance or maximum number of iterations is reached. Problems with difficult convergence properties are not likely to be encountered, but the method will fail with an error after the iteration limit is reached in those cases.

Watch out for the first difference noted above!

2.2 Principal Components

Version 2.1.0 of the package introduces optional arguments and `prcomp`-like function syntax for efficiently computing partial SVDs of matrices after centering and scaling their columns and other adjustments. Use the following arguments to the `irlba` function, or the new `irlba_prcomp` function for PCA:

- **center**: if `center` is a numeric vector with length equal to the number of columns of the matrix, then each column of the matrix has the corresponding value from `center` subtracted from it.

- **scale**: if 'scale' is a numeric vector with length equal to the number of columns of the matrix, then each column is divided by the corresponding value from **scale**.

The following example compares the output of the usual **prcomp** function with output from **irlba**. Note that in general, singular vectors and principal component vectors are only unique up to sign!

```
> set.seed(1)
> x <- matrix(rnorm(200), nrow=20)
> p1 <- prcomp_irlba(x, n=3)
> summary(p1)
Importance of components:
              PC1    PC2    PC3
Standard deviation  1.541 1.2513 1.1916
Proportion of Variance 0.443 0.2921 0.2649
Cumulative Proportion 0.443 0.7351 1.0000

> # Compare with
> p2 <- prcomp(x, tol=0.7)
> summary(p2)
Importance of components:
              PC1    PC2    PC3
Standard deviation  1.541 1.2513 1.1916
Proportion of Variance 0.443 0.2921 0.2649
Cumulative Proportion 0.443 0.7351 1.0000
```

Alternatively, you can compute principal components directly using the singular value decomposition:

```
> p3 <- svd(scale(x, center=colMeans(x), scale=FALSE))
> p4 <- irlba(x, 3, center=colMeans(x))

> # compare with prcomp
> sqrt(crossprod(p1$rotation[,1] - p3$v[,1]))
      [,1]
[1,] 9.773228e-13
> sqrt(crossprod(p1$rotation[,1] + p4$v[,1]))
      [,1]
[1,] 1.652423e-12
```

The implementation of the **center** function argument takes advantage of computational efficiencies in the IRLB algorithm that result in a modest savings of a few vector inner products per iteration compared to a naive implementation using a custom matrix vector product to center the matrix.

2.3 Truncated symmetric eigenvalue decomposition

Use the `partial_eigen` function to estimate a subset of the largest (most positive) eigenvalues and corresponding eigenvectors of a symmetric dense or sparse real-valued matrix. The function is particularly well-suited to estimating the largest eigenvalues and corresponding eigenvectors of symmetric positive semi-definite matrices of the form $A^T A$.

2.4 User-Defined Matrix Multiplication

The `irlba` function includes options for specifying a custom matrix multiplication function. Custom matrix multiplication functions can be used, for example, with the `big.matrix` class from the `bigmemory`/`bigalgebra` packages, or to compute the partial SVD of matrix-free linear operators.

User-defined matrix operations may specified using the optional `mult` parameter. If defined, it must be a function of two arguments that computes matrix vector products. Either argument can be a vector, and the `mult` function must deal with that. The following example illustrates a simple custom matrix function that scales the columns of the matrix, and then compares it with other ways of doing the same thing.

```
> set.seed(1)
> A <- matrix(runif(200), nrow=20)
> col_scale <- 1:10
> mult <- function(x,y)
+   {
+     # check if x is a plain vector
+     if(is.vector(x))
+     {
+       return((x %*% y)/col_scale)
+     }
+     # else x is the matrix
+     x %*% (y/col_scale)
+   }

> irlba(A, 3, mult=mult)$d
[1] 3.1384503 0.9477628 0.4313855

> # Compare with:
> irlba(A, 3, scale=col_scale)$d
[1] 3.1384503 0.9477628 0.4313855

> # Compare with:
> svd(scale(A, scale=col_scale, center=FALSE))$d[1:3]
```

[1] 3.1384503 0.9477628 0.4313855

Alternatively, simply use R's operator overloading methods to define customized matrix vector products. This is the approach taken in the http://bwlewis.github.io/1000_genomes_examples/PCA_whole_genome.html vignette to work with large out of core genomics data. I prefer the simple operator overloading approach and may consider retiring the `mult` function argument in some future package version.

NOTE! When a user-defined matrix multiplication function is used, either using the `mult` argument or through operator overloading, the R reference IRLBA implementation is used instead of the faster C code path in newer package versions.

3 A Quick Summary of the IRLBA Method

3.1 Partial Lanczos Bidiagonalization

Start with a given vector p_1 . Compute m steps of the Lanczos process:

$$\begin{aligned} AP_m &= Q_m B_m \\ A^T Q_m &= P_m B_m^T + r_m e_m^T, \end{aligned}$$

$$B_m \in \mathbf{R}^{m \times m}, P_m \in \mathbf{R}^{n \times m}, Q_m \in \mathbf{R}^{\ell \times m},$$

$$P_m^T P_m = Q_m^T Q_m = I_m,$$

$$r_m \in \mathbf{R}^n, P_m^T r_m = 0,$$

$$P_m = [p_1, p_2, \dots, p_m].$$

3.2 Approximating Partial SVD with A Partial Lanczos bidiagonalization

$$\begin{aligned} A^T A P_m &= A^T Q_m B_m \\ &= P_m \textcolor{blue}{B}_m^T \textcolor{blue}{B}_m + r_m e_m^T B_m, \end{aligned}$$

$$\begin{aligned} A A^T Q_m &= A P_m B_m^T + A r_m e_m^T, \\ &= Q_m \textcolor{blue}{B}_m B_m^T + A r_m e_m^T. \end{aligned}$$

Compute the SVD of B_m :

$$B_m = \sum_{j=1}^m \sigma_j^B u_j^B (v_j^B)^T.$$

$$(\text{i.e., } B_m v_j^B = \sigma_j^B u_j^B, \text{ and } B_m^T u_j^B = \sigma_j^B v_j^B.)$$

$$\text{Define: } \tilde{\sigma}_j := \sigma_j^B, \quad \tilde{u}_j := Q_m u_j^B, \quad \tilde{v}_j := P_m v_j^B.$$

Then:

$$\begin{aligned} A \tilde{v}_j &= A P_m v_j^B \\ &= Q_m B_m v_j^B \\ &= \sigma_j^B Q_m u_j^B \\ &= \tilde{\sigma}_j \tilde{u}_j, \end{aligned}$$

and

$$\begin{aligned} A^T \tilde{u}_j &= A^T Q_m u_j^B \\ &= P_m B_m^T u_j^B + r_m e_m^T u_j^B \\ &= \sigma_j^B P_m v_j^B + r_m e_m^T u_j^B \\ &= \tilde{\sigma}_j \tilde{v}_j + \textcolor{red}{r_m e_m^T u_j^B}. \end{aligned}$$

The part in red above represents the error with respect to the exact SVD. The IRLBA strategy is to iteratively reduce the norm of that error term by augmenting and restarting.

Here is the overall method:

1. Compute the Lanczos process up to step m .
2. Compute $k < m$ approximate singular vectors.
3. Orthogonalize against the approximate singular vectors to get a new starting vector.
4. Continue the Lanczos process with the new starting vector for m more steps.
5. Check for convergence tolerance and exit if met.
6. GOTO 1.

3.3 Sketch of the augmented process...

$$\begin{aligned}\bar{P}_{k+1} &:= [\tilde{v}_1, \tilde{v}_2, \dots, \tilde{v}_k, p_{m+1}], \\ A\bar{P}_{k+1} &= [\tilde{\sigma}_1 \tilde{u}_1, \tilde{\sigma}_1 \tilde{u}_2, \dots, \tilde{\sigma}_k \tilde{u}_k, Ap_{m+1}]\end{aligned}$$

Orthogonalize Ap_{m+1} against $\{\tilde{u}_j\}_{j=1}^k$: $Ap_{m+1} = \sum_{j=1}^k \rho_j \tilde{u}_j + r_k$.

$$\begin{aligned}\bar{Q}_{k+1} &:= [\tilde{u}_1, \tilde{u}_2, \dots, \tilde{u}_k, r_k / \|r_k\|], \\ \bar{B}_{k+1} &:= \begin{bmatrix} \tilde{\sigma}_1 & & & \rho_1 \\ & \tilde{\sigma}_2 & & \rho_2 \\ & & \ddots & \rho_k \\ & & & \|r_k\| \end{bmatrix}. \\ A\bar{P}_{k+1} &= \bar{Q}_{k+1} \bar{B}_{k+1}.\end{aligned}$$
